

# Topological Analysis of Image Data

Team 4 : Kirill Paramonov, Shawn Witte, Pamela Patterson,  
Irene Kim

November 28, 2016

Images with fixed center

Images with random center

Images with semifixed center

# Our Data

- Data is stored as an  $n^2$ -tuple, where  $n$  is the height and width, in pixels, of the grid
- Each entry in the  $n^2$ -tuple is a number between 0 and 1 representing the lightness of a particular pixel (0 is black, 1 is white)
- Brightness is assigned relative to distance from center of pixel to the lines
- Distance between two data points is taken as Euclidean distance between the two points in  $\mathbb{R}^{n^2}$

# Diffusion map

Diffusion: Neat nonlinear dimension reduction algorithm which preserves topology

Generating 4000 images, applying diffusion map

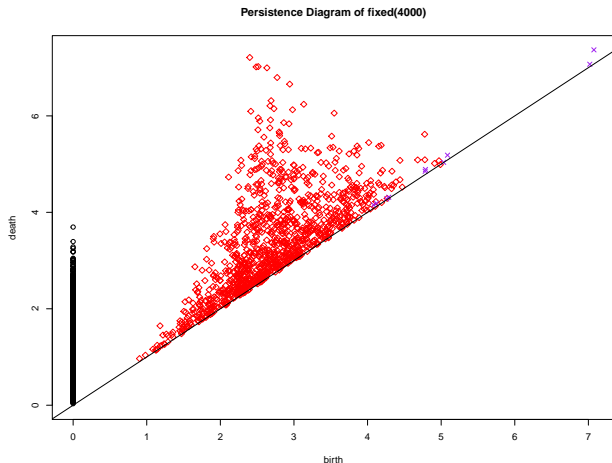

We expect our space to be that of a Möbius strip:

- There are two degrees of freedom:
  - The angle to the bisector (from 0) and the angle between the lines, in which case if the angle between the lines are  $180^\circ$ , there are two choices of bisectors
  - or the angle to each line from 0, where there is an equivalence when the angles are switched
- A Möbius strip has the same homology as  $S^1$  ( $\beta_0 = \beta_1 = 1$ ,  $\beta_i = 0$  for all other  $i$ )

# Persistence Diagram

Persistence diagram of 4000 points without diffusion

# Persistence Diagram

Persistence diagram of 2000 points with diffusion

Dimension=1

Dimension=2

# What if we include noise?

# Noise:continue

# Importance of fade

# Persistence Diagrams

The following were generated without a fixed point.
